From Violence to Voting:
War and political participation in Uganda[*]

Christopher Blattman, Yale University†

First Draft: April 2007

This Draft: September 2008

Abstract:

What is the political legacy of violent conflict? This paper presents evidence for a link from past violence to increased political engagement among ex-combatants. The evidence comes from northern Uganda, where rebel recruitment generated quasi-experimental variation in who was conscripted by abduction. Survey data suggest that abduction leads to substantial increases in voting and community leadership, largely due to elevated levels of violence witnessed. Meanwhile, abduction and violence do not appear to affect non-political participation. These patterns are not easily explained by conventional theories of participation, including mobilization by elites, differential costs, and altruistic preferences. Qualitative interviews suggest that violence may lead to personal growth and political activation, a possibility supported by psychological research on the positive effects of traumatic events. While the generalizability of these results requires more evidence to judge, the findings challenge our understanding of political behavior and point to important new avenues of research.

1. Introduction

What is the political legacy of a violent civil war? Can perpetrators and victims become productive citizens once the fighting stops? Policy-makers are pessimistic. A recent World Bank report sees the individual impacts of civil war as so adverse that they lead to social disintegration (Collier et al. 2003). The French foreign minister recently spoke of young ex-soldiers as "a time bomb that threatens stability and growth" (BBC 2007). And a *New York Times* editorial lamented that such youth return as "damaged, uneducated pariahs" (2006, October 12). Meanwhile, reintegration experts worry that ex-combatants face a life of crime and banditry, and remain alienated and "at war" in their own minds (Richards et al. 2003; Spear 2006). If these commentators are correct, then the rebuilding of society may be all the more challenging and unlikely after war, and could contribute to the well-known 'conflict trap' (Collier 2007).

Not all of the evidence is so gloomy. Psychologists consistently find that victims of violence are in general resilient, and a growing psychological literature finds that experiences of personal growth are more common than distress in the aftermath of violent trauma (Tedeschi and Calhoun 2004). A handful of studies also tie victimization by war violence to greater collective action. Wood (2003), for instance, argues that government violence in El Salvador prompted its' victims to support and even join opposition forces out of moral outrage, while Bellows and Miguel (2006; 2008) find that war violence leads to greater political participation and awareness in Sierra Leonean households.

Little of this evidence, however, proves a causal link from violence to political engagement, and even less concerns the perpetrators. Yet violence is endemic in the developing world; civil conflict has afflicted more than half of all nations since 1945, with a fifth suffering ten or more years of war (Blattman and Miguel forthcoming). In the burgeoning conflict literature, however, the impact of voting on violence receives more attention that the reverse (Snyder 2000; Wilkinson 2004).

This paper employs new data and a tragic natural experiment in northern Uganda to quantify the socio-political impacts of combat experiences and war violence. Patterns of rebel abduction during Uganda's twenty year war appear to have generated nearly exogenous variation in recruitment. If so, causal estimates of its impact on later-life outcomes such as political participation can be identified.

The results defy expectations and suggest that forced recruitment leads to greater post-war political participation—a 28% increase in the likelihood of voting and a doubling of the likelihood of being a community leader among former abductees. Abduction, however, does not generally affect non-political forms of social participation, suggesting that the effects of war on participation may be uniquely political.

Of course, conscription simply represents a package of war experiences: violence, military training, indoctrination, time away, and so forth. Analysis of self-reported experiences suggests that exposure to violence, in particular violence witnessed, accounts for most of the impact of abduction on participation. No other war experiences have similar explanatory power.

This finding is good news for policy makers in war-torn nations. For social scientists, however, it presents a puzzle: why would violence lead to positive political engagement? Conventional explanations—ones that focus on the costs of voting, or elite mobilization—find little support in the data. Interviews with local leaders and former combatants, however, yield narratives of personal transformation and activation, narratives that echo a psychological literature on 'post-traumatic growth'. This paper explores the alternative empirical and theoretical links between violence and voting and sets out an important agenda for research in political behavior and psychology.

2. War, abduction, and politics in northern Uganda

In 1988, a spirit medium named Joseph Kony assembled the remnants of several failed insurgent groups from northern Uganda into a new force, the Lord's Resistance Army, or LRA.[3] Locally Kony is believed to possess great spiritual powers, and his stated goal is to seek a spiritual cleansing of the nation. Kony's movement, however, is also rooted in a longstanding political, economic, and ethnic divide. Following Independence, northern peoples (including the Acholi, to which Kony and the LRA belong) dominated the military, while southerners dominated the commercial sector. For more than two decades, this martial power enabled a series of brutal northern dictators to govern the nation. In 1986, however, a

---

[3] This account is based on Allen (2005), Beber and Blattman (2008), Behrend (1999), Doom and Vlassenroot (1999), Finnström (2008), Lamwaka (2002), and Omara-Otunnu (1994).

young politician named Yoweri Museveni led a southern rebel force to overthrow the Acholi-dominated government. Several guerrilla forces in the north initially resisted Museveni's takeover, but for the most part settled for peace or were defeated by 1988. The handful of fighters that would not settle for peace gathered under Kony to continue the fight.

In spite of widespread antipathy for Museveni, the LRA attracted little support from other Acholi, and the poverty and unpopularity of the movement led to reliance on forced recruitment. From its earliest days the rebels looted homes and abducted youth to obtain supplies and recruits.

In 1994 the Sudanese government began supplying the LRA with supplies, weapons and territory upon which to build bases—support that enlarged and invigorated a small and weak LRA. Abduction from 1995 to 2004 was large-scale and indiscriminate, with at least 60,000 to 80,000 youth estimated to have been taken by the LRA for at least a day (Annan et al. 2006; Pham et al. 2007). The majority were adolescent males, though men and women of all ages were commonly taken.

Twenty percent of male abductees did not return and sadly can be presumed perished (as few remain with the LRA). The remaining 80% escaped, were released, or were rescued after periods of a day up to ten years. Roughly half of these 'returnees' reported to and were demobilized by the Ugandan army (the UPDF), and two in five returnees passed through a 'reception center' that provided basic health services, family relocation, and reinsertion. In 2006 the Government of Uganda and the LRA reached a fragile truce and peace talks (and skirmishes) continue at this time.

The two decades of instability and economic destruction in the north stand in stark contrast to the success and stability of the rest of Uganda. Outside Acholiland, violence has abated, infrastructure has expanded, HIV infection rates have fallen, and economic growth has been a robust 6% for the past decade (Government of Uganda 2007).

3. Data & measurement

The data come from Phase I of the Survey of War Affected Youth (SWAY), a representative survey of male youth (ages 14 to 30) in eight rural sub-counties of the districts of Kitgum and Pader. Data were collected in 2005-06 by the author, a psychologist, and local research assistants.

To account for migration and mortality, the survey selected its respondents from a sample frame of youth living in the region *before* the conflict. 1162 households were sampled from U.N. World Food Programme lists compiled in 2002, and 88% of household heads were tracked down and interviewed. Enumerators worked with household heads to develop a retrospective roster of all youth living in the household in 1996—a year chosen as it was easily recalled as the date of the first election since 1980.

A sample of 881 surviving male youth was drawn from these retrospective rosters. Nearly half of the youth had moved since 1996 and were tracked across the region. Surveyors located 741, or 84%. Former abductees were over-sampled, with 462 interviewed in total. Absentee questionnaires were conducted with the families of young men that had died or were not found to correct for observable determinants of attrition.[4] Survey summary statistics are listed in Table 1.

Measuring participation

The survey includes three indicators of political participation. First, a national referendum was held immediately the survey on the question of opening Uganda to multi-party politics.[5] 46% of survey respondents over age 18 say they *Voted in the 2005* referendum, a rate comparable to national turnout levels. Second, five percent of youth report that they are a *Community mobilizer*—elected members of the community who are responsible for organizing the community for daily or weekly meetings.[6] Finally, four respondents (0.4%) hold an official *Political job*, such as a village councilperson or county administrator.

The survey also sought indicators of community participation. 42% report *Membership in any community group*, including *peace groups* (6%), *water management committees* (1.6%), *cultural groups* (16%), *sports teams* (11%),

---

[4] There are two types of unfound youth: absentees that could not be tracked down, and those that did not return from abduction. Enumerators interviewed the families of all but about 11 absentees, and virtually all were reported to be engaged in work or school away from home. Those that did not return from abduction comprise 20% of all abductees, 95% of which can be presumed perished given the small number of abductees still with the armed group.

[5] This referendum asked voters: "Do you agree to open up the political space to allow those who wish to join different organizations/parties to do so to compete for political power?"

[6] The mobilizer is the most common form of youth leadership, and is an unpaid community service. Every few years communities hold a meeting and solicit nominations. Nominees give a short speech and are elected by a show of hands.

farmer's cooperatives (11%), *school clubs and committees* (6%), and *church or bible study groups* (18%). 78% also *Attend church* regularly, and 5% of youth *Volunteer* for a community organization.

Last, the survey measured self-reported anti-social and aggressive behaviors. Acholi culture stresses obedience to elders, and 7% indicated that they *Disobey elders*. The survey also measures 11 self-reported pro-social behaviors (e.g. enjoying working with peers, or being helpful to the community) and we construct an indicator for those in the *Bottom quartile of the pro-social distribution*.[7] Finally, the survey asked whether respondents had been in a *Physical fight* in the past six months (7%), whether they were *Ever quarrelsome* (5%), and whether they *Ever threatened to hurt others* (2%).

Measuring war experiences

More than two in five male youth reported an *Abduction* of any length. Many of these abductions were short, often because the youth was too young or old. Such youth were often released after giving directions or carrying loot. *Months Abducted* ranged from a day to 10 years, averaging 9.3 months.

The LRA routinely used violence to intimidate and control civilians and abductees. To gauge respondents' levels of exposure to violence, the survey asked about 25 of the most common *Violent acts experienced*, including 6 acts *witnessed*, 6 *received*, 8 *perpetrated* by the respondent, and 5 inflicted *upon family* members of the respondent by the LRA.[8] The average abductee reported 11 different violent acts versus non-abductees' 5.2 acts. Most youth, for example, witnessed killings, experienced their homes being raided, or taking cover from gunfire. Among the abducted, forced labor, thrashings, and imprisonment were commonplace. Attempts to escaped were punished with beatings or death, a sentence other abductees were often forced to carry out with machetes or clubs. Initiation to the LRA also involved forced violence:

---

[7] The psychosocial survey questions are based on an adapted version of the Northern Ugandan Child and Youth Psychosocial Adjustment Scale (Loughry and MacMullin 2002)

[8] The survey recorded an indicator for ever experiencing each act, and each index is a sum of these indicators. Acts received include: gunfire; forced labor; beatings; armed attacked; being tied up; and receiving a war. Acts witnessed include: regular gunfire; beatings or torture; attacks or battles; killings; massacres; rape; and the torching of occupied homes. Acts perpetrated include: beating a civilian; beating family or friends; killing a soldier; killing a civilian; killing family or friends; forcible sex; and abuse of dead bodies. Violence upon family includes: abducted parent; other abducted family; family member with war injury; violent death of a parent; and violent death of other family or friends.

25% of abductees were made to harm or kill a civilian and 23% were made to desecrate dead bodies—a deeply held taboo. Finally, 13.5% of abductees report being forced to beat or kill family or friends. Such violence served to break down a youth's defenses, desensitize him to violence, and dissuade him from escape.

Other war experiences recorded include indicators for whether the youth held a *Leadership position* or rank (9%), ever *Carried his own firearm* (32%), and whether he *Passed through a reception center* (39%). Such centers were set up by local and international NGOs after 1999 to receive youth returning from long abductions. Just 22% of abductees *Received services* from NGOs after returning home.

Qualitative data

Prior to the survey, the author conducted two months of semi-structured interviews with approximately 120 youth (roughly 80 of whom were former abductees) plus more than 60 community members and leaders. The interviews focused on abduction patterns, LRA organization, and return and reintegration experiences. Interviews aimed to understand the conduct of the war, investigate the validity of the causal identification strategy, and develop reintegration metrics and hypotheses. Interview subjects were typically contacted through community leaders and reception center staff, and so were not systematically selected. 15 former LRA junior officers (e.g. a lieutenant) were located and interviewed in this way.

Following the survey and preliminary analysis, the author conducted 10 days of semi-structured interviews to explore the meaning and validity of the socio-political survey results. Interviews were conducted in three of the eight enumeration areas and included all survey respondents recorded as community mobilizers or having political jobs, all former abductees holding any rank, as well as a random sample of 20 respondents (half whom voted in the 2005 referendum and half whom did not). Also interviewed were reception center workers, local political operatives, and poll workers from the same areas.

Finally, concurrent with the survey, a psychologist and a local social worker conducted systematic, semi-structured interviews and psychosocial assessments of a non-random subsample of 30 youth and their families. The details of this qualitative psychosocial study are reported in Annan et al. (2008) and relevant results are highlighted in this paper.

4. The impact of abduction on participation

Empirical strategy

Estimating the impacts of military service and war violence is a difficult task. Combatants are usually unlike non-combatants in unobservable ways, and so any comparison will conflate the impacts of war with pre-existing differences that led the youth to join or be selected by the armed group. This is especially true if the characteristics associated with being a combatant (such as poverty, social exclusion, or malleability) are traits that also affect social consciousness or political activity.

One solution is the counterfactual approach, where a relevant control group is found for recruits. The estimated impact, however, is only as reliable as the counterfactual. Causal estimates will be unbiased only when recruitment is 'conditionally unconfounded' or exogenous—that is, when all selection is on observed traits (Rubin 1978; Rosenbaum and Rubin 1983; Imbens 2004).

In most wars, such stringent conditions would not hold. Evidence from Uganda, however, suggests that the most common types of selection into armed groups are not present in the case of the LRA. First, volunteering (or self-selection) into the LRA was virtually unknown, and volunteers comprised less than half of one percent of all LRA recruits. Moreover, nearly all of these volunteers joined before 1991, and most come from a neighboring district, Gulu (and so do not influence this paper's sample).

Second, interviews with the leaders of LRA raiding parties suggest that by neither design nor accident did they abduct a select group of youth. From their Sudanese bases, rebels ventured into Uganda for weeks at a time in groups of roughly 15 fighters. Raiding parties had two aims: ambushing government forces and raiding homesteads along their path for food and recruits. Abduction targets tended to be unplanned and arbitrary, and homesteads were raided regardless of wealth or makeup. Typical of East Africa, rural Acholi households live in relatively isolated homesteads in their fields, arrangements which made them particularly vulnerable to LRA raids. Rebels usually invaded such homesteads at night, abducting all able-bodied people to carry looted goods. These abduction parties were under instruction to release only young children and older adults, but to keep all adolescent and young adult males.

The data support these claims. The survey gathered data on pre-war household wealth (including land and livestock) and parent's education, occupation, and death—traits that are believed to be reliable predictors of participation in armed groups in Africa (e.g. Cohn and Goodwin-Gill 1994; Honwana 2005; Humphreys and Weinstein 2008). If we compare the abducted and non-abducted along such pre-war traits we observe little difference in conditional mean differences at even the 10% significance level (Table 2, Column 1). Abducted youth differ only by year of birth (as expected) and pre-war household size.[9]

These same household traits, however, help predict participation in a voluntary government militia, implying that if abduction were associated with these pre-war characteristics we would have the statistical power to observe it. Five percent of youth were current or past militia members. A comparison of pre-war traits shows that militia members came from poorer and more agricultural households (Table 2, Column 2), and collectively the pre-war covariates strongly predict government militia membership—the effects are larger than in the abduction case and jointly significant (p = 0.98).

A remaining concern is selective attrition. There are two main types of 'attritors': non-survivors and unfound migrants. The 84% tracking success rate meets or exceeds the rates achieved by several 'gold-standard' youth tracking surveys in poor countries (Thomas et al. 2001; Hamory and Miguel 2006). Also, similar proportions of abducted and non-abducted youth were found (29.7% versus 28.3%). Even so, differential attrition patterns raise concern: non-abducted youth are more like to have migrated and gone unfound, while abductees are uniquely likely to have been abducted and not returned (and can be assumed perished given the small number of abductees still with the LRA). Estimates of the impact of abduction will be biased if qualities that determine migration or survival also shape political action.

To correct for attrition on observables, we collected demographic data and data on current activities and well-being from the surviving family members. Following Fitzgerald et al. (1998), these data were

---

[9] The significance is driven by households greater than 25 in number, perhaps because small bands of raiders were hesitant to raid large, difficult-to-control groups. Otherwise, differences in the distributions of predicted abduction probabilities among abducted and non-abducted youth are driven by year and location of birth alone. In a logit regression of abduction on pre-war traits, omission of household traits does not affect the distribution of the predicted probabilities, and they are jointly not significance (p = 0.18).

used to calculate attrition probabilities, and regression estimates are weighted by the inverse of these attrition probabilities to eliminate bias from attrition on observed traits.

Results

Assuming conditional unconfoundedness, consistent estimates of the causal impact of abduction can be calculated using a index model such as a probit, weighted by a non-parametric estimate of the selection probability, or propensity score (Hirano et al. 2003).[10] These results are displayed in Table 3.

To begin, abduction leads to an 11 percentage point increase in the probability a youth over 18 voted in the 2005 referendum (Column 2), significant at the 1% level. Since just 40% of eligible non-abducted youth voted (Column 1), this ATE represents a 28% increase in voter turnout (Column 3).

Abduction also leads to a 3.4 percentage point increase in the likelihood that a youth is a community mobilizer, significant at the 1% level. Just 3% of non-abducted youth are leaders, and so the impact of abduction represents a 106% increase in levels of leadership.

Abduction is also associated with an 160% increase in the likelihood of holding a political job such as a community councilmember or appointee. The estimate, however, is not statistically significant due to sample size: only four respondents reported such employment, three of whom are former abductees. The direction and magnitude of the result is nonetheless consistent with the other political results.

Turning to others forms of community participation, the causal impacts of abduction on various forms of group membership are either small or not statistically significant. Participation in a sporting organization is less commonly reported among abductees, although the result is only significant at the 10% level. Only in one instance, peace groups, is there a significant impact of abduction. Peace groups are

---

[10] In this case, Y^* is a latent variable describing an individual i's propensity for participation, observed as a binary outcome, Y. The treatment effect, τ, can be estimated by the following regression:

$$P(Y_i = 1) = \Phi(\tau \cdot T_i + X^S_i \cdot \beta_l),$$

where the treatment (i.e. abduction) indicator T equals one if youth i was abducted, and the X^S are the subset of observed covariates X that are significantly correlated with Y, conditional on treatment. The weights used are:

$$\omega_i = \omega(T_i, v_i, \rho_i) = \rho_i \cdot \pi_i \cdot \left(\frac{T_i}{\hat{e}(v_i)} + \frac{1-T_i}{1-\hat{e}(v_i)} \right)$$

where ρ_i and π_i are sampling and attrition weights, and $\hat{e}(v_i)$ is a nonparametric estimate of the propensity score. The v_i are the subset of the covariates X_i that have substantial correlation with the treatment.

clubs of youth that stage cultural dances, dramatic presentations, debates, and talks, often with peace-building or reconciliation themes, and abducted youth are nearly twice as likely to be members (97%).

Finally, there is mixed evidence of greater anti-social or aggressive behavior among abductees. Abductees are slightly less likely to report that they engaged in a fight or exhibit anti-social behavior, although neither result is significant. Meanwhile, they are more likely to report that they disobey elders, threaten others, or are quarrelsome. In the case of threatening others, the result is large and significant at the 10 percent level: just one percent of non-abducted youth report this behavior compared to roughly 3 percent of abductees.

One risk, of course, is that hostile attitudes and behaviors are systematically underreported, thus increasing standard errors and biasing coefficients downwards (especially if measurement error is higher among abductees). Nonetheless, even underreporting of a grand magnitude—such as two in three youth failing to report aggressiveness—would still imply that aggression is small in absolute terms.

The above estimates are robust to alternative specifications, including the removal of the control variables, the non-parametric selection weights, and the attrition correction (results not displayed).

Discussion

First and foremost, the popular picture of former combatants—damaged, alienated, and potentially violent—finds little support in these data. Rather, former abductees are just as likely to belong to social groups as the non-abducted, and just as unlikely to report anti-social behaviors.

Several qualitative studies echo these results. For instance, a psychosocial study of northern Ugandan youth by Annan et al. (2008) finds that abductees commonly reported problems with family or community immediately upon return, but that such reintegration problems diminished rapidly with time. Families and communities were generally welcoming, and more than 95% of the abducted youth in the sample returned home. In their studies of Acholi cosmology and reconciliation processes, Baines (2005) and Harlacher et al. (2006) argue that such reintegration was facilitated by a cultural ethos of reconciliation and a public campaign for forgiveness and acceptance by public officials, religious leaders, and NGOs.

Similarly high rates of community reconciliation and acceptance have also been reported in countries such as Sierra Leone (e.g. Wessells 2006; Williamson 2006).

Most surprising, the analysis suggests that abduction leads to a substantial increase in levels of political engagement. The survey's measures of political participation are admittedly limited in scope, confined to voting, community leadership, and political jobs, and hence some caution is warranted. In each of these cases, however, the impacts of abduction on political participation are relatively large. The increase in voting among abductees is comparable to the average effect of compulsory voting laws in a sample of 324 international elections (Blais and Dobrzynska 1998). Abduction's impact is also orders of magnitude greater than the average impacts of canvassing and other turnout efforts in U.S. elections (Gerber and Green 2000; Green and Gerber 2004). Unfortunately, comparable African benchmarks do not exist.

The evidence also suggests that abductees' community engagement is generally positive and civic in nature. Community mobilization is a productive role in the village, undertaken by the most confident and public-minded youth. Voting in the 2005 referendum was peaceful overall, and the measure received broad support, with 92% of national voters supporting the measure (IFES 2007). The survey did not track politically contentious outcomes, however, and so we cannot exclude the possibility that abductees are also more politically contentious or polarized.

We do observe some evidence of elevated aggression in abductees in the form of threats (although not in reports of fighting or anti-social behavior). Self-reported threats are not significantly correlated with voting and community mobilization, however, suggesting the more aggressive youth are not the same as those that are politically active. The incidence of such hostility is also very small in absolute terms. Indeed, psychosocial studies in Uganda have emphasized the contrary: abducted youth ten to respond passively in response to harassment or aggression in order to avoid stigma, signal their peacefulness to the wider community, avoid painful memories of the war, and, in some cases, for fear of their own potential for aggression (Veale and Stavrou 2007; Annan et al. 2008).

The remainder of the paper explores possible rationales for the relationship between abduction and political participation. Before doing so, however, it is worth asking whether the impacts we observe could be spurious—the result of unobserved selection effects rather than changes in behavior. Several

11

plausible sources of bias exist. For instance, the impacts on political participation would be overstated if more politically active youth were more likely to join (or be targeted by) the LRA, or if the less clever, confident, or politically engaged abductees were more likely to be killed. While such selection is unknowable, we can engage in a thought experiment, asking how influential such bias would have to be in order to account for the effects we observe. The Appendix describes the results of two forms of formal sensitivity analysis. One models unobserved selection into the LRA, and finds that even an unobserved factor as influential as our primary determinants of abduction—age and location—would reduce but not eliminate the impact of abduction on voting, leaving the general conclusion intact. A second method estimates the degree of selective non-return from abduction that would be required to generate the impact we observe, and finds that rates of turnout among non-returned abductees would have to be zero in order for the selection story to drive the impacts we observe. Such scenarios are extremely unlikely.

5. Unpacking the causal mechanism

Abduction by the LRA represents a bundle of war experiences. To unpack the mechanism linking abduction to participation, we can look for relationships between participation and war experiences among former abductees. Table 4 displays regressions of a subset of the participation and aggression indicators on war experiences, including violent acts, abduction length (including a linear length term and an indicator for short abductions of two weeks or less[11]), and indicators for whether the abductee carried his own firearm, held a leadership position, passed through a reception center, or later received services.

Two caveats are in order. First, unlike abduction, war experiences may not be exogenous, meaning the estimates could be biased. War experiences, violence in particular, are also measured with error. Our indices of violence record incidence, not frequency, and so they systematically understate the number of acts ever experienced. Abductees may also not admit their most terrible experiences. Such systematic

---

[11] Use of a "short abduction" indicator and a linear months abducted term controls for non-linearities in the relationship between abduction length and participation. Alternative methods—the use of a log abduction length term, or the use of multiple dummy variables for alternative lengths—yield comparable results.

error would increase standard errors and bias the violence coefficient towards zero, in which case the Table 4 estimates should be considered a lower bound on the influence of violence on participation.[12]

Results

Abductees who witnessed the most acts of violence are the most likely to participate politically later in life. Each additional act of violence witnessed is associated with a 4.3 percentage point increase in the probability of voting and a 2.1 percentage point increase in the probability of being a community mobilizer, both significant at the 5% level at least (Columns 1 and 2). Are these effects large? The average abducted youth reports 1.8 more acts of violence witnessed than non-abducted youth, and so the coefficients in Table 4 imply that violence witnessed is associated with a 7.6 percentage point increase in voting among abductees (68% of abduction's total impact, as seen in Table 3) and a 3.8 percentage point increase in community mobilization (115% of abduction's impact).

We do not, however, see a consistently significant relationship between violence witnessed and community group membership (Column 3), nor do we see a significant relationship with physical fights or other quarrels. Violence witnessed is, however, associated with reporting having ever threatened others; the coefficient in table 4 implies that abduction is associated with a 3 percentage point increase in the likelihood of threatening others, which is approximately 1.5 times the impact of abduction estimated in Table 3. The relationship is significant at only the 10 percent level, however.

Abductees who experienced more family violence are also more likely to vote and be a community mobilizer (although the result is statistically significant for mobilization alone). While the coefficients are large in absolute terms, abductees and non-abductees report nearly identical levels of family violence (see Table 1). Thus such acts cannot be responsible for the impact of abduction on political participation we observe in Table 3.

---

[12] Even if the bias were in the opposite direction, measurement error is still unlikely to account for the correlation we observe. For systematic measurement error to alter the conclusions, it must be associated with both abduction and the outcome of interest, not simply abduction, and must be sufficiently large to change the conclusion. Measurement error can be seen as an omitted variable, and thus considered in the sensitivity analysis in Figure 1. As with other omitted variables, the amount of measurement error needed to change the coefficient by an order of magnitude is implausibly large.

Looking at other war experiences, none are as robustly and as consistently related to our measures of political participation as is violence witnessed. Neither the violence received, violence perpetrated, nor abduction length measures are consistently or significantly associated with political participation, community group membership, or aggression.

Having carried a firearm is negatively related to both voting and community mobilization, although the effect is significant for mobilization alone, and even then at only the 10 percent level. Having held a leadership position in the LRA is associated with a large, 22.7 percentage point decrease in the probability of voting. There is no substantive relationship between leadership and the other measures of participation and aggression, however. Finally, former abductees who passed through a reception center or received NGO services later on do not appear to be more likely to politically participate, and there is no systematic, strong and significant association with other forms of participation and aggression.

Discussion

The analysis suggests that violence, especially violence witnessed, is the main mechanism by which abduction impacts political participation: acts witnessed are strongly and significantly associated with voting and mobilization; acts witnessed differ between abducted and non-abducted youth; and they can account for the bulk of the impact of abduction on voting and mobilization. Violence against family is a key determinant of participation among abductees, but cannot explain the gap with non-abductees.

This pattern holds if we examine the relationship between abduction and violence among all youth, including the non-abducted. In a regression of voting and community mobilization on violence, abduction, and abduction length (see Table 5) a youth who witnessed an additional act of violence is 3.7 percentage points more likely to vote and 1.2 percentage points more likely to be a community mobilizer. Youth whose family experiences an additional act of violence are also 1.7 percentage points more likely to be a community mobilizer. As with abductees alone, youth who receive or perpetrate greater violence do not appear to participate any more or less.

The remainder of the paper explores the possible explanations between violence witnessed and political participation. It is worth noting, however, that this link may not be unique to Uganda. Bellows and

Miguel (2008) observe similar patterns in Sierra Leone: civilians whose household experienced a killing, maiming, or displacement are more likely to attend community meetings, more likely to join political groups, and more likely to vote than peers. Similarly, Carmil and Breznitz (1990) survey Jewish Holocaust survivors alongside a control group of their Israeli peers and find that survivors support more centrist political parties, express a greater belief in God, and a greater belief in a better future. Thus the link we observe in Uganda could be part of a more general phenomenon.

6. Alternative explanations and mechanisms

What theories of political behavior could explain such patterns? While it is difficult to prove a particular mechanism or channel is at work with the evidence at hand, we can begin by eliminating some of the plausible alternatives.

Mobilization by elites or NGOs

Mobilization of youth by elites, parties, and NGOs is common in Africa, and the mobilization of ex-combatants has been documented in instances such as the 2007 election in Sierra Leone (Christensen and Utas 2008). Such groups can mobilize participation using social pressure or material goods (e.g. Uhlaner 1989; Shachar and Nalebuff 1999; Green and Gerber 2004).

Mobilization is an unlikely account of abductee participation in Uganda, however. First, no voter mobilization efforts were observed by the author, local research assistants, or the community leaders interviewed. Indeed, at the time of the referendum, opposition parties were not yet allowed to organize, and turnout efforts are also outlawed on voting day. Second, community mobilizer elections are held outside the normal political cycle, and are unrelated to party affiliation. Community members typically nominate several candidates, followed by a vote. None of the leaders interviewed could recall interference from political elites or discussion of political affiliations during these informal elections.

Third, the main indicators of interaction with NGOs—having passed through a reception center or received NGO services—are uncorrelated with voting and community participation (see Table 4). If NGOs mobilized former abductees, they did not do so using their registries.

15

Finally, participation is associated with a relatively unobservable trait—violence witnessed—and not with a more easily observed marker of abduction, such as abduction itself, or length of abduction. It is difficult to believe that youth were mobilized on the basis of such a hidden trait.

Differential costs

Simple rational theories of participation suggest that it is decreasing in shoe leather and opportunity costs (Riker and Ordeshook 1968; Feddersen 2004). If these costs are lower among abductees, or the recipients of violence, it might account for the higher participation we observe. Proxies for higher shoe leather costs include indicators for not living in one's district of origin—for instance having *Migrated to a town* or *Migrated out of district*. Bad health could also impede participation, measured using an *Injury indicator* and an indicator for being in the *Top quartile of emotional distress* proxy. Finally, opportunity cost is proxied by an *Asset index*, *Days employed*, and *Gross earnings*.

Logically, any factor responsible for the patterns we observe must meet four conditions: (1) it must differ between abducted and non-abducted youth; (2) it must be correlated with voting and mobilization; and (3) it should be associated with violence witnessed. Table 6 assesses the explanatory power of each of the proxies, calculating the difference between abductees and non-abductees and the correlation with three participation variables. Only one of these proxies, serious injuries, meets the criteria, albeit the sign is in the "wrong" direction: abductees are more likely to be injured, but injured youth are less likely to be mobilizers. Hence abductees' heightened leadership comes in spite of their costly injuries, not because of them. None of the other proxies for shoe leather and opportunity costs appear influential.

Altered social preferences

Other participation theorists have proposed that individuals have altruistic preferences and take into account the benefit of their actions to others (e.g. Harsanyi 1977; Harsanyi 1992; Feddersen and Sandroni 2002; Edlin et al. 2007). Military conditioning, or violent or near-death experiences, could in principle alter such preferences and increase participation among abductees. If so, we should observe that individuals who participate politically also make other social contributions, such as public goods management (e.g. school and water groups) or being a volunteer. We might also expect to observe higher levels of

pro-social behavior, such as respectfulness and cooperation. The survey measures both *pro-social behavior* and an *Index of social support received*. According to the estimates in Table 6, abductees do not exhibit greater social contributions or group participation, and pro-social behavior and social support are actually lower. We see no evidence of a general shifts in altruism.

Augmented information

Finally, a set of theories propose that informed voters are more likely to participate (e.g. Feddersen and Pesendorfer 1999). Information is proxied by indicators for *Functional literacy*, *Radio ownership*, and *Educational attainment*, all included in Table 6. Abductees, however, are considerably less (not more) likely to be literate, educated, or own a radio. Moreover, none of these traits are closely associated with voting, suggesting that formal education and information are not the channel of impact. Naturally this analysis does not preclude the influence of other types of information or experience. War and abduction is undoubtedly a learning experience, one that may transform the perceived costs and benefits of participation. But the simple education-voting correlation seen in the U.S. is not replicated here.

7. What the abductees say

To better understand the role of abduction and violence in political participation, we turn to interviews with former abductees, leaders, social workers, and political party operators. As discussed in section 3, the qualitative evidence is limited in scope. Even so, several patterns emerged from the semi-structured interviews.

First, several abducted youth described, after return, a sense of power over their lives and events. Abductees commonly witnessed terrible acts and even came close to death themselves. One youth emphasized that after such experiences, he felt he could face anything in civilian life. Another spoke of 'making up for lost time', and a third spoke of finding purpose after the violence—a sense he was 'chosen'.

The decision to escape from the LRA in particular was framed in language of self-determination and control. Several youth described a turning point where the 'scales fell from their eyes', whereupon they realized that the propaganda fed to them by the rebel leadership—the righteousness of violence, or the

seizure of the government—was false. In some cases this realization was associated with witnessing or experiencing a terrible and seemingly senseless act of violence. In a crucial act of self-determination, the youth took back control of their lives and decided to run away.

Interviews with elders and other community leaders yielded similar sentiments. According to a reception center social worker, who also worked as an election poll supervisor during the previous two elections, formerly abducted youth "feel like they can take control of their lives," and "are subjected to hardship where… they mature very fast." Asked their opinion of formerly abducted youth, elders and leaders from several different villages explained that abduction (and violence in particular) is an experience that "matured" abducted youth and made them "more serious". These same terms are ones commonly used in Acholi culture to describe the difference between a boy and a man. The experience of violence was thus associated with local processes of maturation.

Not all abducted youth expressed an increased sense of control. The majority of youth (abducted or not) took pains to highlight their idleness, helplessness, and despair. At the time of the field work, all respondents (like the entire rural population of Acholiland) had been displaced from their homes and livelihoods for at least four years. Few places on earth are poorer or more desperate. Abductee accounts of marginal gains in control and outlook must be considered against this backdrop of misery.[13]

A second rationale for abductees' leadership is their comfort with public speaking and airing their opinion to others. Acholi leaders commonly attributed their own role in the community, and their nomination to elected positions, to such confidence and skills. Likewise, one elder suggested that war trauma gave abducted youth "courage to speak their minds" while a poll and social worker emphasized that former abductees "comfortably speak their views in a group of people or a crowd." The informants attributed these behaviors to the training and experience in the LRA, as well as the confidence borne of experience as a fighter.

---

[13] Also, while abduction is associated with greater control over the present and future, an absence of *past* control is associated with resilience. Abductees commonly and successfully coped with traumatic memories by attributing their ordeals to 'God's will', suggesting that they were not responsible for their acts. An absence of self-blame was strongly associated with psychological resilience, as was an ability to "forget" bad experiences and focus on the future (Annan et al. 2008).

Such accounts suggest a change in both perspective and ability. That is, in addition to a change in self-regard, abductees may have acquired leadership skills in the bush, and so they lead at home because they are more able (rather than simply more optimistic or confident). The evidence for skills and experience, however, is weak. First, we do not observe a strong correlation between political participation and leadership roles in the LRA. If anything, leadership is associated with less participation, at least in the form of voter turnout (see Table 4). Second, there is little systematic relationship between abduction length (another reasonable proxy for experience) and political engagement. Third, if skills are the relevant channel, the link to violence witnessed is not clear. A change in personal goals, perspective, or self-regard, while impossible to prove, is more consistent with the patterns we observe.

Theoretical interpretations

There are at least three plausible interpretations of the interview accounts. The first draws on a body of psychological research on positive responses to traumatic experiences. Traditionally, psychologists have focused on the damaging effects of violent trauma (as well as the widespread resilience to such experiences).[14] Yet in case after case of traumatic experience—including fatal diseases, rape, assault, house fires, plane crashes, war violence, and loss of a loved one—reports of "post-traumatic growth" experiences consistently outnumber reports of psychiatric disorders (Tedeschi and Calhoun 2004).

Indeed, a growing body of case evidence suggests that there are five major domains of personal growth after traumatic experiences: a greater appreciation of life and changed sense of priorities; warmer, more intimate relationships with others; a greater sense of personal strength; recognition of new possibilities or paths for one's life; and spiritual development (e.g. Tedeschi and Calhoun 1996; Emmons et al. 1998; Nolen-Hoeksema and Davis 2002; Haidt 2006).

A small number of these studies look specifically at the victims of war violence, finding self-reported levels of personal growth among Yugoslav refugees (Powell et al. 2003), U.S. Second World War veterans (Elder and Clipp 1989), U.S. prisoners of war in Vietnam (Sledge et al. 1980), and Israeli adolescents

---

[14] Studies commonly find that only a minority of victims develop long term emotional distress and other disorders (e.g. Elder and Clipp 1989; King et al. 1998; Luthar et al. 2000; Masten 2001).

exposed to terror incidents (Laufer and Solomon 2006). In most cases the degree of growth is positively associated with the harshness of the violence. These studies argue that surviving a traumatic event unleashes several processes: it reveals hidden abilities and changes one's self-concept; it initiates a personal evaluation and shifts goals and priorities; and it shatters previous belief systems and leads to a struggle to make meaning from the experience.

These studies do not, however, distinguish between different forms of victimization—whether violence witnessed, received, or upon the family. Accounts of post-traumatic growth also have several weaknesses: they are typically self-reported, difficult to verify, and must be taken at face value (Tennen and Affleck 1998). Comparison groups are also seldom employed. The parallel to abductees' political accounts is nonetheless striking.

A second possible interpretation come from "expressive" theories of participation, where individuals are presumed to value the act of political expression itself (Downs 1957; Riker and Ordeshook 1968; Fiorina 1976). The origin of such preferences, and the reasons for variation across people and time, are poorly understood. If post-traumatic growth theorists are correct, however, the reordering of personal goals and priorities after witnessing a traumatic event could alter one's information set, expectations, or tastes for participation in proportion to the trauma received. Like theories of post-traumatic growth, however, expressive preferences (and changes) are difficult to test or disprove. Also, the specific link to violence witnessed remains a puzzle.

Finally, traumatic events may not simply change perceptions, but actually provide concrete information and experience. Former abductees may be better informed of the costs of conflict than their peers. They have also travelled widely, and met people of different countries and cultures. They have learned to fight, to work as a group towards common goals, and have proven their mettle in escaping from the rebel group. Such experience may not only change the calculus of participation, but also the personal returns to collective action. While the potential relationship between these abilities and violence received is not clear, we cannot dismiss the possibility of a link.

8. Conclusions and directions for future research

Survey evidence from Uganda suggests that the victims of violence are just as likely as their peers to participate socially, just as unlikely to behave aggressively, and considerably more likely to vote and lead in their communities. A similar link between violence and voting has been observed in Sierra Leone and Israel. It is a link, however, that is difficult to decipher. Several obvious channels of impact, such as mobilization of the disaffected, find little support. Meanwhile, interviews with the youth yield narratives of newfound self-control, confidence and skills. Such accounts, while far from conclusive, nonetheless mesh with psychological theories of post-traumatic growth and political evidence on expressive voting.

The evidence from Uganda thus focuses attention on an important avenue of future research: the psychological foundations of political engagement, the sources of interpersonal variation, and the effects of experience, particularly traumatic experiences, on political attitudes and participation.

Such traumatic experiences are tragically common. Violence is endemic in developing countries. Among ex-combatants in particular, forced recruitment and the controlled use of violence is at least as common in fighting forces as the use of voluntary participation and rewards (Weinstein 2007; Beber and Blattman 2008; Humphreys and Weinstein 2008). The LRA, which is frequently mischaracterized as an irrational and barbaric rebel group, is far from unique in this regard.[15] Hence these findings may have (hopeful) implications for millions of fighters in dozens of war-torn countries, especially in Africa. To the extent that positive political engagement also springs from violence against civilians, many millions more may be affected in the same way.

There are important limits, however, on this paper's results. First, the political outcomes measured in the survey are few in number, and so we should take caution in generalizing the findings to political participation more broadly. The determinants of other forms of political participation may differ.

---

[15] Anthropologists and political scientists that study the LRA take a different view, finding the guerrilla force to be much more conventional and strategic in its use of violence and spirituality than is represented by the Ugandan government and Western media (e.g. see Lamwaka 2002; Okello 2002; Allen and Vlassenroot 2008; Blattman and Annan 2008; Branch 2008; Finnström 2008; Finnström 2008; Mwenda 2008; Schomerus 2008; Titeca 2008)

Second, the results in this paper arise from data on male Ugandan youth, and may not apply to females or older adults, let alone other regions. Even so, the similarity between the Ugandan results and those from refugees and victims of war violence in other countries suggest some degree of external validity. Generalization of the results awaits more data collection in more situations of violence and conflict.

Finally, a more important question remains unanswered: why in Uganda did violence lead to peaceful and productive rather than contentious participation? The answer is undoubtedly culturally and institutionally specific. Several aspects of Ugandan institutions and culture may have led to the generally positive political engagement we see: a functioning, relatively democratic government at the national and local level; vigorous and open local political systems that are inclusive of youth; and a society that generally welcomed former abductees back into the community. In the absence of any of these conditions, post-traumatic participation may have been muted or even destructive. Studies of young ex-combatants in Sierra Leone and Liberia, for instance, are considerably less optimistic about their positive political engagement, and even find evidence of violent electoral participation (Utas 2003; Bøås and Hatløy 2006; Christensen and Utas 2008). There are few more important questions in political science that who works peacefully within the system, who turns to violence, and why.

In spite of these caveats, this paper's findings suggest some important general lessons. If nothing else, we have seen that the proclivity for participation varies among individuals; they are malleable; and they can be shaped in systematic and predictable ways. Violence and hardship may be particularly influential, and in an unexpected direction: a positive one. In this conclusion we may have been preceded by Shakespeare: "Sweet are the uses of adversity," he wrote, "Which like the toad, ugly and venomous / Wears yet a precious jewel in his head.[16]

Appendix: Sensitivity analysis

This appendix explores the sensitivity of the impacts of abduction (estimated in Table 3) to violations of some of the fundamental identification conditions, and illustrates that only under extreme and unlikely circumstances could the results we observe be generated by unobserved selection into the armed group, or selective attrition.

First, we can employ a method of sensitivity analysis based on Imbens (2003) that explicitly models a degree of unobserved selection into the armed group. Figure 1 plots each of the observed pre-war control variables on two axes: a vertical axis that indicates the increase in explained variation (i.e. the increase in the R^2 statistic) that comes from adding the control to a regression of voting on all other controls; and a horizontal axis that indicates the influence of each control in explaining variation in abduction. Influence in both is a prerequisite for inducing a selection effect. As expected, only the year and location of birth indicators substantially influence both abduction and voting.

We can also engage in a thought experiment: model a *hypothetical* unobserved variable U, and ask how influential it would need to be to reduce the impact on voting by a substantial amount. In essence this U represents any source of self-selection, or selection on the part of the LRA, which we fear may lead to bias in the result. The question is then how much bias, relative to the observed covariates, would be enough to change out conclusions?

The downward sloping curve in Figure 1 represents all the combinations of: (i) correlation between U and abduction, and (ii) correlation between U and voting, that would be sufficient to halve the observed impact of abduction on voting.[17] The curve is therefore a threshold, beyond which our hypothetical U is influential enough to significantly reduce our result (although, we should note, still leave the direction and general magnitude of the impact intact). Only our age and location indicators exceed the threshold,

---

[17] The unobservable in question is modeled as a binomial variable independent of all other covariates that is assumed to have a logistic conditional distribution with both voting and abduction.

implying our hypothetical unobservable would need to be as influential as the primary determinants of abduction just to halve the observed treatment effect.

Another form of sensitivity analysis allows us to consider the potential effects of selective attrition. One option would be to follow Manski (1990) or Lee (2005) and estimate nonparametric bounds on the impact of abduction. Doing so leaves the general conclusions relatively unchanged, however, since attrition levels are nearly identical in the two groups. It is attrition patterns that differ. In particular, the abducted are uniquely likely not to return from abduction (almost all of whom can be presumed perished) while the non-abducted are more likely to have otherwise died, or migrated and remain unfound.

We can perform a second thought experiment to consider whether the treatment effects we observe could be accounted for by different forms of selective attrition. For instance, what if voter turnout among non-abductees (40%) is the "true" level of turnout among all youth, observed or not? What degree of selective return from abduction would be required to lead us to erroneously observe 51% turnout among former abductees? The answer is none: rates of voter turnout among unreturned abductees would have to be zero in order for there to be no difference in turnout between abducted and non-abducted youth.[18] A hypothetical turnout of 25% among unreturned abductees, meanwhile, would be sufficient to halve the estimated impact of abduction on voting, from 11 percentage points to 5.5. Even under such extreme assumptions, the general direction, magnitude and significance of the impacts would not change.

---

[18] To calculate this amount, we assume 40% turnout among all youth that died or are absentees, and calculate the impact of abduction for the full sample of youth in the 1996 sample assuming different levels of turnout among unreturned abductees. A rate of zero turnout is required to reduce the impact of abduction on voting to zero.

Figures in bold represent correlates that exhibit a statistically significant ATE (at the 5 percent level) in Column 1 and a statistically significant relationship with the measure of participation (either Columns 2 or 4).

† Each item in Column 1 is a separate regression. Each ATE is calculated as the coefficient on an abduction indicator variable in an ordinary least squares regression of the dependent variable on abduction and controls (age and location dummies, age/location interactions, and pre-treatment individual and household characteristics). Weights include inverse sampling probabilities and inverse attrition probabilities.

‡ Calculated as the ATE in Column 1 multiplied by the coefficient in Column 2, divided by the relevant ATE in Table 3.

Figure 1: Impact of relaxing the assumption of unconfoundedness

Selection bias that would be induced by the omission of an observed covariates relative to the threshold where a independent binomial covariate would induce selection bias sufficient to reduce the ATE by half
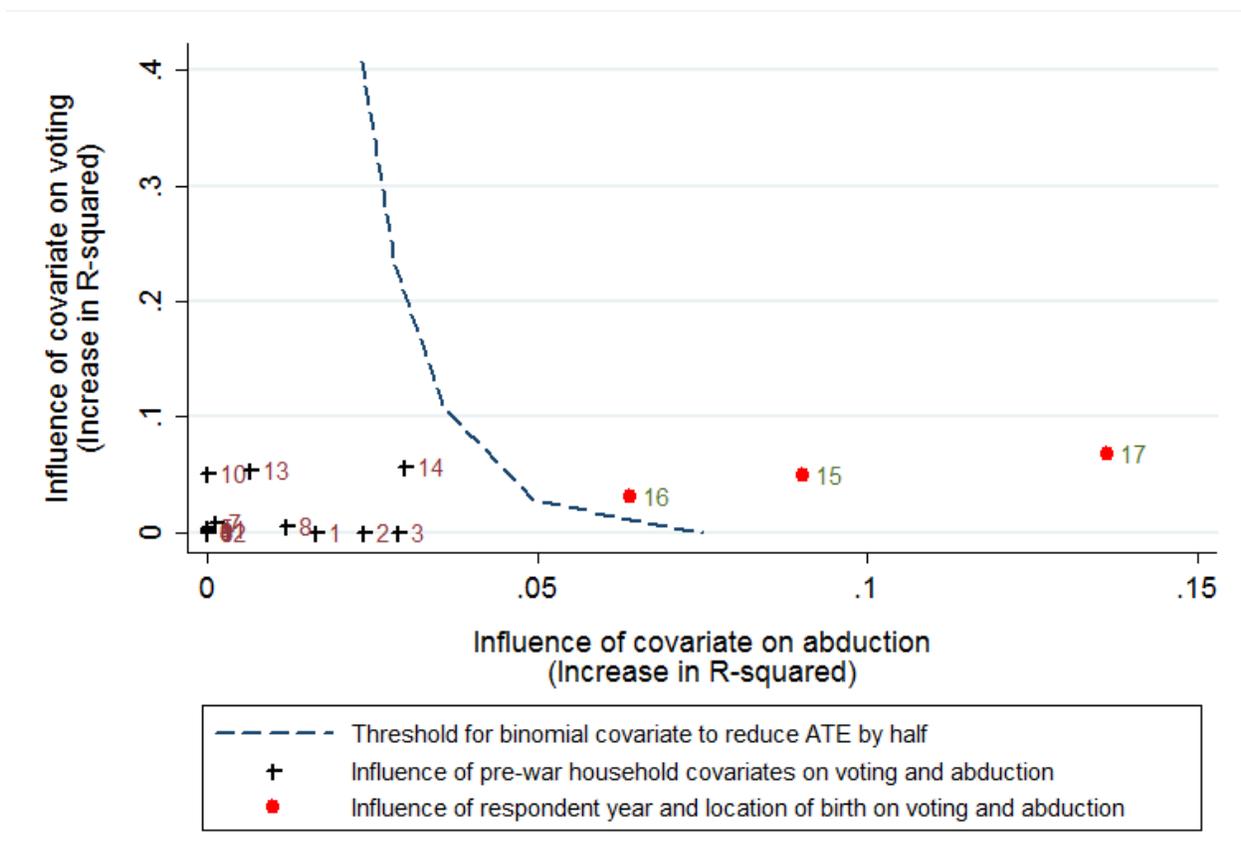

Notes: Each **+** and **•** represents a pre-treatment covariate (listed below), plotted according to its additional explanatory power for treatment assignment (on the horizontal axis) and its explanatory power for the outcome (vertical axis), which in this case is the voting indicator. Each axis measures the change in the R^2 statistic from adding the covariate to the ATE regression. The downward sloping curve represents the locus of points at which any independent binomial unobserved covariate would have sufficient association with both treatment and the outcome to reduce the ATE on voting by half.

Influence of observed covariates (numbers refer to **+** and **•** in Figure 1):

1.	Mother's Education	10.	Household cattle stock in 1996
2.	Father's Education	11.	Household other livestock in 1996
3.	Mother's & Father's Education	12.	Household plow ownership in 1996
4.	Father died before 1996	13.	All household assets in 1996
5.	Mother died before 1996	14.	All household characteristics
6.	Both parents died before 1996	15.	Respondent year of birth
7.	One or both parents died before 1996	16.	Respondent location of birth
8.	Household size in 1996	17.	Respondent year and location of birth
9.	Household landholdings in 1996
